

ABSTRACT OF THE DISCLOSURE

A negative film setter has film holders for having set therein films to be fed. Each of the film holders has both a detecting sensor for detecting whether a film is set therein and a lamp which is lit when a film is set in a film holder and which is not lit when a film is not set therein. Therefore, a user can determine at a glance whether or not films are set in the film holders, thus allowing the user to skillfully set a plurality of films at film setting sections. Accordingly, due to detection by the detecting sensor, the negative film setter can recognize in which film holder a film is set, and films can be fed in a sequential order.
